### 4.8. Trigonometric Functions

### 4.8.1. Basic definitions

In a plane the angles of a triangle add up to $\alpha+\beta+\gamma=$ $180^{\circ}$, and in a right-angled triangle with $\gamma=90^{\circ}$ we have $\alpha+\beta=90^{\circ}$.
Two right-angled triangles are similar with equal side ratios if they have equal angles $\alpha$ or $\beta$. Consequently the following side ratios depend only on one angle $\alpha$ or $\beta$ and are called trigonometric functions:

Sine: $\sin (\alpha)=\frac{a}{c}=\cos (\beta)$
Cosine: $\cos (\alpha)=\frac{b}{c}=\sin (\beta)$
Tangent: $\tan (\alpha)=\frac{a}{b}=\frac{1}{\tan (\beta)}$

The values of these ratios can be obtained from an electronic calculator and are used to calculate the missing data of a rightangle triangle if one side and either an angle or a second side are given.

## Example 1

Given are $\mathrm{a}=4 \mathrm{~cm}$ und $\alpha=40^{\circ}$. Calculate $\mathrm{b}, \mathrm{c}$ and $\beta$.

## Solution

Angle sum: $\underline{\beta}=90^{\circ}-\alpha=\underline{50^{\circ}}$
Sine: $\sin (\alpha)=\frac{\mathrm{a}}{\mathrm{c}} \Leftrightarrow \underline{\mathrm{c}}=\frac{\mathrm{a}}{\sin (\alpha)}=\frac{4 \mathrm{~cm}}{\sin \left(40^{\circ}\right)} \approx \underline{6,22 \mathrm{~cm}}$
Pythagoras: $a^{2}+b^{2}=c^{2} \Rightarrow \underline{b}=\sqrt{c^{2}-a^{2}} \approx \underline{5,22 \mathrm{~cm}}$

## Example 2

Given are $\mathrm{a}=5 \mathrm{~cm}$ und $\mathrm{c}=8 \mathrm{~cm}$. Calculate $\mathrm{b}, \alpha$ and $\beta$.

## Solution

Sine: $\sin (\alpha)=\frac{\mathrm{a}}{\mathrm{c}} \Leftrightarrow \underline{\alpha}=\sin ^{-1}\left(\frac{\mathrm{a}}{\mathrm{c}}\right)=\sin ^{-1}\left(\frac{5}{8}\right) \approx \underline{38,7^{\circ}}$
Angle sum: $\underline{\beta}=90^{\circ}-\alpha=\underline{51,3^{\circ}}$
Pythagoras: $\mathrm{a}^{2}+\mathrm{b}^{2}=\mathrm{c}^{2} \Rightarrow \underline{\mathrm{~b}}=\sqrt{\mathrm{c}^{2}-\mathrm{a}^{2}}=\sqrt{39} \underline{\mathrm{~cm}}$

Exercises on trigonometric functions No. 1

### 4.8.2. Basic relations

## Theorem

In a right-angled triangle $\left(0 \leq \alpha, \beta \leq 90^{\circ}\right)$ we have the following obvious identities:

1. $\sin (\alpha)=\cos (\beta)=\cos \left(90^{\circ}-\alpha\right)$
2. $\tan (\alpha)=\frac{a}{b}=\frac{c}{c} \frac{\sin (\alpha)}{\cos (\alpha)}=\frac{\sin (\alpha)}{\cos (\alpha)}$
3. Pythagoras: $\mathrm{a}^{2}+\mathrm{b}^{2}=\mathrm{c}^{2} \Leftrightarrow\left(\frac{\mathrm{a}}{\mathrm{c}}\right)^{2}+\left(\frac{\mathrm{b}}{\mathrm{c}}\right)^{2}=1 \Leftrightarrow[\sin (\alpha)]^{2}+[\cos (\alpha)]^{2}=1$

Exercises on trigonometric functions No. 2-5

### 4.8.3. Measuring angles in radians

## Definition

The subdivision of the full cycle into 360 degrees is highly arbitrary and does not allow the approximation of the trigonometric functions in terms of simple polynomials. However the trigonometric functions become compatible with polynomials when the angle is expressed in radians instead of degrees.
The radian of an angle $\alpha$ is defined as the arc length of the corresponding sector in the unit circle with radius $r=1$. Since a full cycle of $360^{\circ}$ corresponds to the circumference $2 \pi r=2 \pi$ of the unit circle and likewise a half cycle of $180^{\circ}$ has an arc length of $\pi$, we can convert degrees into radians and vice versa with the formula:

$$
\alpha \text { in radian }=\frac{\pi}{180} \cdot \alpha \text { in degree. }
$$

Exercises on trigonometric functions No. 6

### 4.8.4. Graphs of the trigonometric functions

## Definition

Let $\mathrm{P}(\mathrm{x} \mid \mathrm{y})$ the endpoint of a pointer in the unit circle (i.e. radius $\mathrm{r}=1$, which rotates to an angle $\alpha \in \mathbb{R}$ counterclockwise ( $\alpha$ $>0)$ resp. clockwise $(\alpha<0)$ starting from the horizontal position. Then the right-angled triangle under the pointer has the hypotenuse 1 so that the trigonometric functions become $\sin (\alpha)=y, \cos (\alpha)=x$ und $\tan (\alpha)=\frac{y}{x}$

Example: Graphs of the trigonometric functions No. 1

### 4.8.5. Properties of the trigonometric functions

Definition: A function f is periodic with period $\mathbf{T}$, if its course is repeated after each period T , i.e.

$$
f(x)=f(x+T) \text { for all } x \in D
$$

Example: Graphs of the trigonometric functions No. 2

| Function <br> $\mathbf{f}(\alpha)=$ | Symmetry <br> $\mathbf{f}(-\alpha)=$ | Neighbor angle <br> $\mathbf{f}(\boldsymbol{\pi}-\boldsymbol{\alpha})=$ | Period <br> $\mathbf{T}=$ | Domain <br> $\mathbf{D}=$ | Range <br> $\mathbf{W}=$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\sin (\boldsymbol{\alpha})$ | $-\mathrm{f}(\alpha)$ <br> (uneven) | $\mathrm{f}(\alpha)$ | $2 \pi$ | $\mathbb{R}$ | $[-1 ; 1]$ |
| $\cos (\boldsymbol{\alpha})$ | $\mathrm{f}(\alpha)$ <br> $($ even $)$ | $-\mathrm{f}(\alpha)$ | $2 \pi$ | $\mathbb{R}$ | $[-1 ; 1]$ |
| $\tan (\alpha)$ | $-\mathrm{f}(\alpha)$ <br> (uneven) | $-\mathrm{f}(\alpha)$ | $\pi$ | $\mathbb{R} \backslash\left\{\frac{\pi}{2}+\mathrm{z} \cdot \pi: \mathrm{z} \in \mathbb{Z}\right\}$ | $\mathbb{R}$ |

### 4.8.6. Angular velocity and amplitude

Examples: Exercises on trigonometric functions No. 7 a

## Angular velocity and period

The pointer moves with constant angular velocity $\omega=\frac{\alpha}{t}$.
At a given time $t$ the angle is $\alpha=\omega \cdot \mathrm{t}$ and the vertical height is $y(t)=\sin (\alpha)=\sin (\omega \cdot t)$.
The pointer needs exactly one period T for a complete cycle with angle $\alpha=2 \pi$.
Therefore the angular velocity is $\omega=\frac{2 \pi}{\mathrm{~T}}$.
When the pointer moves faster the angular velocity $\omega$ increases but the period $\mathrm{T}=\frac{2 \pi}{\omega}$ decreases.

Examples: Exercises on trigonometric Functions No. $7 b$

## The amplitude

The length of the pointer defines the range of the sine function and is called amplitude $\mathbf{A}$.
At a given time $t$ the vertical height of a pointer with length A moving with angular velocity $\omega$ is

$$
y(t)=A \cdot \sin (\omega \cdot t)
$$

### 4.8.7. Vertical shift and phase

Examples: Exercises on trigonometric functions No. 7c

## The phase

If the pointer starts late, his delay is called the phase $\mathbf{t}_{0}$. Accordingly the graph starts with a delay or horizontal shift of $t_{0}$. The formula is

$$
y(t)=A \cdot \sin \left[\omega\left(t-t_{0}\right)\right]
$$

Examples: Exercises on trigonometric functions No. 7d

## The vertical shift

If the pointer starts its movement at the height $y_{0}$ the graph follows
and is shifted vertically Its formula is

$$
\mathrm{y}(\mathrm{t})=\mathrm{A} \cdot \sin \left[\omega\left(\mathrm{t}-\mathrm{t}_{0}\right)\right]+\mathrm{y}_{0}
$$

with
A = amplitude = length of pointer
$\omega=$ angular velocity of pointer
$\mathrm{T}=$ period $=$ duration of one complete turn
$\mathrm{t}_{0}=$ phase $=$ delay of pointer $=$ horizontal shift
$y_{0}=$ vertical shift

### 4.8.8. The sine rule

## Theorem (sine rule):

In any triangle we have $\frac{\sin (\alpha)}{\mathrm{a}}=\frac{\sin (\beta)}{\mathrm{b}}=\frac{\sin (\gamma)}{\mathrm{c}}$.
"The larger the angle the longer the opposite side"
Proof for acute angles (for obtuse angles use supplementary angle):

$\mathrm{h}_{\mathrm{c}}=\mathrm{b} \cdot \sin (\alpha)=\mathrm{a} \cdot \sin (\beta) \Leftrightarrow \mathrm{b} \cdot \sin (\alpha)=\mathrm{a} \cdot \sin (\beta) \Leftrightarrow \frac{\sin (\alpha)}{\mathrm{a}}=\frac{\sin (\beta)}{\mathrm{b}}$.
Exercises on Trigonometric Functions No. 9 and 10

### 4.8.9. The cosine rule

Theorem (cosine rule)
In any triangle we have $c^{2}=a^{2}+b^{2}-2 \cdot a \cdot b \cdot \cos (\gamma)$

## commentary:

The cosine rule ist he generalization of Pythagoras' theorem for angles $\gamma \neq 90^{\circ}$ :
a) For acute angles $\gamma<90^{\circ}$ we have $\cos (\gamma)>0$
$\Rightarrow$ additional term $-2 \mathrm{ab} \cdot \cos (\gamma)<0$,
$\Rightarrow \mathrm{c}$ is shorter than with Pythagoras. (light trangle)
b) For right angles $\gamma=90^{\circ}$ we have $\cos (\gamma)=0$
$\Rightarrow$ additional term $-2 \mathrm{ab} \cdot \cos (\gamma)=0$,
Pythagoras: $\mathrm{c}^{2}=\mathrm{a}^{2}+\mathrm{b}^{2}$. (middle trangle)
c) For obtuse angles $\gamma>90^{\circ}$ we have $\cos (\gamma)<0$

$\Rightarrow$ additional term $-2 \mathrm{ab} \cdot \cos (\gamma)>0$,
$\Rightarrow \mathrm{c}$ is longer than with Pythagoras (dark triangle)
Proof for acute angles (for obtuse angles use supplementary angle):

$$
\begin{aligned}
\mathrm{c}^{2} & =\mathrm{h}_{\mathrm{a}}{ }^{2}+\mathrm{p}^{2} & & \mid \mathrm{h}_{\mathrm{a}}=\mathrm{b} \cdot \sin (\gamma) \text { bzw. } \mathrm{p}=\mathrm{a}-\mathrm{q} \\
& =(\mathrm{b} \cdot \sin (\gamma))^{2}+(\mathrm{a}-\mathrm{q})^{2} & & \mid \text { expand } \\
& =(\mathrm{b} \cdot \sin (\gamma))^{2}+\mathrm{a}^{2}-2 \mathrm{aq}+\mathrm{q}^{2} & & \mid \mathrm{q}=\mathrm{b} \cdot \cos (\gamma) \\
& =\mathrm{b}^{2} \cdot(\sin (\gamma))^{2}+\mathrm{a}^{2}-2 \cdot \mathrm{a} \cdot \mathrm{~b} \cdot \cos (\gamma)+\mathrm{b}^{2} \cdot(\cos (\gamma))^{2} & & \mid \operatorname{common} \text { factor } \mathrm{b}^{2} \\
& =\mathrm{b}^{2} \cdot\left[(\sin (\gamma))^{2}+(\cos (\gamma))^{2}\right]+\mathrm{a}^{2}-2 \cdot \mathrm{a} \cdot \mathrm{~b} \cdot \cos (\gamma) & & \mid \text { Pythagoras } \\
& =\mathrm{a}^{2}+\mathrm{b}^{2}-2 \cdot \mathrm{a} \cdot \mathrm{~b} \cdot \cos (\gamma) & &
\end{aligned}
$$
